#### Main goal

We try to make use of powerful tools of the classical thermodynamics in order to investigate dynamical states of an hydrodynamical isothermal turbulent self-gravitating system.

 Our main assumption, inspired by the paper of Keto et al (2020), is that turbulent kinetic energy can be substituted for the macro-temperature of chaotic motion of fluid elements.

As a proper sample for our system we use a model of turbulent self-gravitating isothermal molecular cloud which is at final stages of its life-cycle, when the dynamics is nearly in steady state.

### Molecular Clouds – the birth places of stars Self-gravitating turbulent fluids

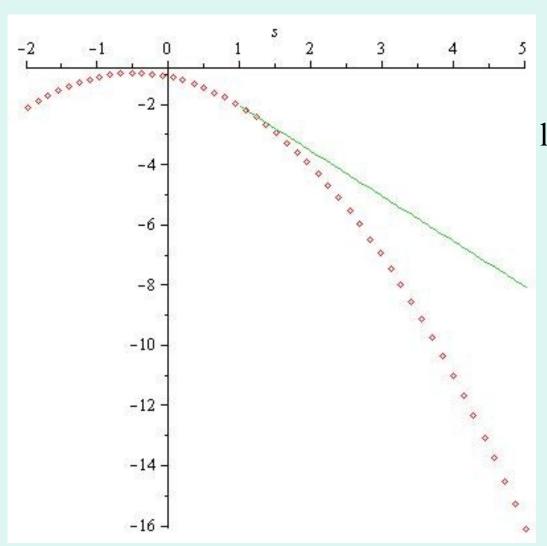

- How much is it important to understand the star-formation process?
- We can explain IMF, SFR, SFE and → the evolution of Galaxy

#### Molecular Clouds - Physical parameters and classification

	GIANT MOLE- CULAR CLOUD COMPLEX	MOLECULAR CLOUD	STAR- FORMING CLUMP	PROTO- STELLAR CORE <sup>d</sup>
Size (pc)	10 - 60	2 - 20	0.1 - 2	$\lesssim 0.1$
Density $(n(H_2)/cm^3)$	100 - 500	$10^2 - 10^4$	$10^3 - 10^5$	$> 10^5$
Mass (M <sub>☉</sub> )	$10^4 - 10^6$	$10^2 - 10^4$	$10 - 10^3$	0.1 - 10
Line width (km s <sup>-1</sup> )	5 - 15	1 - 10	0.3 - 3	0.1 - 0.7
Temperature (K)	7 - 15	10 - 30	10 - 30	7 - 15
Examples	W51, W3, M17,	L1641, L1630,		see
	Orion-Monoceros,	W33, W3A,		Section 4.3
	Taurus-Auriga-	B227, L1495,		
	Perseus complex	L1529		

<sup>\*</sup> Protostellar cores in the "prestellar" phase, i.e. before the formation of the protostar in its interior.

## PDF of mass-density Lognormal – turbulence (isothermal) PL-tail- turbulence and gravity

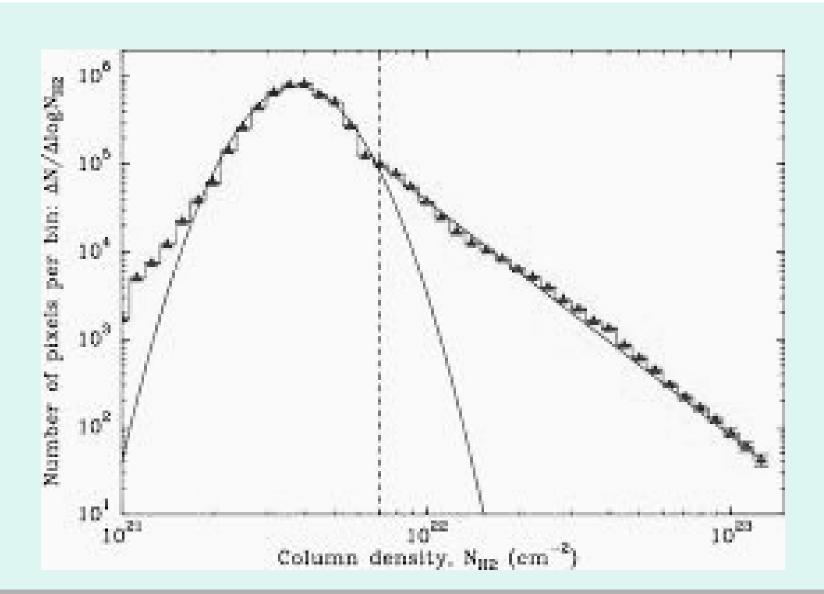

lognormal 
$$\propto \exp\left(-\frac{\left(s-\frac{-}{s}\right)^2}{2\sigma^2}\right)$$

$$s = \ln(\rho/\rho_0)$$

PL-tail 
$$\propto \exp(qs)$$
;  $q < 0$ 

## PDF of mass-density Lognormal – turbulence (isothermal) PL-tail- turbulence and gravity

#### The abstract scale

$$l(s) \equiv l_c \left[ \int_{s}^{\infty} p(s') ds' \right]^{1/3}$$

#### **Our model – the MC physics**

- Turbulence fully developed and saturated; there exists an inertial range of scales:  $l_d \le l \le l_{uv}$
- Gravity self-gravity and gravity from the surrounding medium
- Thermodynamics isothermal equilibrium
- Magnetic fields and feedback from young stars are neglected
- The turbulence locally is homogeneous and isotropic  $\rightarrow$  the motion of fluid elements is purely chaotic
- → This local motion can be modeled as a perfect gas of fluid elements

#### Our main idea

■ Turbulent kinetic energy ← → Macro temperature of the chaotic motion of fluid elements (Keto et al. 2020)

$$\frac{1}{2}m\sigma(l)^2 \equiv \frac{3}{2}\kappa\theta(l)$$

m - the mass of a fluid element  $\sigma(l)$  - the turbulent velocity dispersion

#### **Our model**

 We regard at every scale a physically small (homogeneous) volume

$$l_d \leq l \leq l_c$$
 ,  $V_0 << l^3$ 

The gravitational potential in this volume

$$\varphi(l) = \varphi_s(l) + \varphi_m$$
  
 $\varphi_s(l)$  - the self - gravity  
 $\varphi_m$  - the potential due to surrounding medium

#### Model – the internal energy of the small volume

$$\varepsilon(l) = \frac{3}{2}N(l)\kappa\theta(l) + \frac{3}{2}\frac{m}{m_0}N(l)\kappa T + mN(l)\varphi(l)$$

#### **Equations – the entropy 1**

$$d\varepsilon = \frac{3}{2}N\kappa d\theta + \left[\frac{3}{2}\kappa\theta + \frac{3}{2}\frac{m}{m_0}\kappa T + m\varphi\right]dN$$

 $d\varepsilon = \theta ds - P dV_0 + \mu dN - First Law$  $V_0$  and N are const.

$$\Rightarrow ds = \frac{3N\kappa}{2} \frac{N\kappa}{\theta} d\theta$$

#### **Equations – the entropy 2**

$$\Rightarrow s(\theta, N) = \frac{3}{2} N \kappa \ln \left( \theta / \theta_d \right)$$

 $\theta_d$  - the macro - temperature at disipation scale  $l_d$  Third Law:

 $s(\theta_d, N) = 0$  - the entropy at disipation scale  $l_d$ 

#### **Equations – the free energy**

$$f(\theta,N) = \varepsilon(\theta,N) - \theta s(\theta,N)$$

$$\Rightarrow f(\theta, N) = \frac{3}{2} N \kappa \theta \left[ 1 - \ln(\theta/\theta_d) \right] +$$

$$+\frac{3}{2}\frac{m}{m_0}N\kappa T+mN\varphi$$

#### **Equations – the Gibbs energy**

$$g(\theta,N)=\varepsilon(\theta,N)-\theta s(\theta,N)+PV_0$$

$$\Rightarrow g(\theta, N) = \frac{3}{2} N \kappa \theta \left[ \frac{5}{3} - \ln(\theta / \theta_d) \right] + \frac{3}{2} \frac{m}{m_0} N \kappa T + m N \varphi$$

 $PV_0 = N\kappa\theta$  - Clapeyron - Mendeleev equ. for the macro - gas

- Boundary conditions for the cloud fixed macro-temperature, pressure, and number of fluid elements
- The small physical volume is set at the same conditions in regard to its surrounding medium → hence it is a grand canonical ensemble
- Therefore the relevant potential is the Gibbs energy

$$g = g(\theta, N, V_0)$$

Starting from the Gibbs energy set in a non-equilibrium form

$$g(\theta, N, V_0) = \varepsilon(\theta, N) - \theta_0 s(\theta, N) + P_0 V_0$$

We take the partial derivatives in regard to macro-temperature and volume and set them to zero to obtain the conditions for extremum

$$\left(\frac{\partial g}{\partial \theta}\right)_{N,V_0} = 0 \rightarrow \theta = \theta_0 ; \left(\frac{\partial g}{\partial V_0}\right)_{\theta,N} = 0 \rightarrow P = P_0$$

 The kind of the extremum depends on the sign of the functuonal determinant D (which elements are the second partial derivatives calculated at the extremum point)

$$D = \frac{3}{2} \left( \frac{N\kappa}{V_0} \right)^2 > 0$$

■ D is positive → hence the Gibbs energy has a minimum → The system (small volume) resides at a stable dynamical state

What can one conclude for the whole cloud?

-> We have obtained the cloud's medium is locally dynamically stable, and hence the macro-temperature and pressure change continuously through the fluid, then large parcels of the cloud will be stable.

-> For the whole cloud the latter conclusion will be valid if the macro-temperature and pressure change through the cloud boundary without jumps.

#### **Conclusions**

This novel approach, inspired by the work of Keto at al. (2020), shows the ability of the classical thermodynamics to give a fiducial description of the equilibrium dynamical states of one hydrodynamical isothermal turbulent self-gravitating system, represented here by a molecular cloud model.

Despite of several approximations concerning the presented physical picture we consider our attempt as a sensible step in this direction.
